

I make the phone stand, actually the tablet stand, because that's the most thing that I would use. And the tablet stand can also be very simple and easy to make. Because since we're first using the laser cutting machine, I want to have a simple design that won't cause a lot of trouble for the laser cutting machine. And for the other two options, I imagine both of them will get quite complex.

I want my design to be simple, and I made the tablet stand possible to produce with the tool we have. It also matched my goal of making something I would actually use. What worked well was that the design stayed manageable for my first laser cutting project. It only takes the machine one minute to cut the cardboard. And because of this, I was able to produce five or six iterations to refine my sketch.

This project considered on desirability and usability.

- Desirability:
I chose the tablet stand because I could really use it in daily life. I can use it for watching videos, reading, or doing work. That made the design feel more worth making. The other two ideas seemed more complicated, and I did not think I would use them much.
- Usability:
The stand was simple, so it was easy to understand and easy to use. A tablet can sit on it without much trouble. The design was also easier to cut and put together, which was good for a first laser cutting project.

What did not work well was the challenge of balancing simplicity with rigidity. A very simple design can sometimes limit extra details. I also realized that I need to take the material itself for consideration. the cardboard It's firm in the beginning, but after you bend it, it lose its structure and becomes softer and softer. The project got some feedback from my peers, both compliments and some suggestions on how I should improve. I'm advised to increase the strength of the overall structure. And the feedback also made me reflect on how to make a product that can be sustained to use for a while.

Overall, I learned that a good design is not always the most complicated idea, and not always the most simple idea either. We just need to consider what's practical and what's easy to make, and how to make a high-quality object. If I continue this project, I would explore small improvements by strengthening the structure.
